1 Introduction

This is the introduction.

2 Notes on all of the circuit designs in Verilog

All of the designs are created using pure Verilog code and tested through Free and Open-Source Software (FOSS). The decision to opt for FOSS was deliberate, aiming to prevent any vendor-locking to specific hardware or predefined IPs. Predefined IPs are often optimized by a specific hardware vendor and intended for use with that vendor's hardware. However, the hardware may not always be available or suitable for a specific application. Academics and numerous companies opt for open-source and open-hardware approaches to prevent vendor lock-in. Once the design and algorithm are thoroughly understood, they can be initially implemented without any specific platform in mind. Later, when selecting the device vendor, the design can be modified to suit the specific hardware requirements.

That is why Verilog, with Cocotb [1] (Test Bench creation tool) and Verilator [2] (simulator) have been used for designing the circuits presented in this paper.

3 Calculating the division of fixed point numbers

Typically, when employing numerical methods to solve transcendental equations, the calculation of the division of two input numbers becomes necessary. This requirement persists even when applying the Newton-Raphson (NR) method to solve a set of two equations, as it entails computing the reciprocal value of the Jacobian determinant.

There are some IP blocks available, which are capable of calculating the division of two numbers, but the blocks are usually either vendor specific intellectual property IP [**amd-xilinx-vivado-divider-ip-block**] or feature low performance [3].

The drawback of vendor-specific IPs lies in their limited compatibility, often preventing their use with FPGA chips from different vendors. On the other hand the vendor specific IPs are usually optimized and able to use the specific type of resources available at the vendor's chip which resolve in better performance.

To preserve the compatibility of the design with chips from multiple vendors, the custom solution for division design based on the very known Newton Raphson (NR) algorithm was developed. [3]

3.1 Newton Rapshon algorithm for calculating the division

General Newton Raphson (NR) algorithm is a well known approach to numerically solve equations. It is the reason why it is utilized in many algorithms. However, the negative aspect of NR is that it's convergency strongly depends on initial values of unknown variables. When the initial variables are chosen poorly, the performed number of iterations before the convergency is reached can be high.

To reach the fastest convergency possible (determined in number of iterations) apart from the scaling the dominator into the interval [0.5,1] the initial value calculation formula should be utilized. [3] The formula for calculating the initial value eq. 3 - 1 is applied after the scaling of denominator is performed. The algorithm developed for the appropriate scaling is explained in the *Calculating number of bits to shift the denominator*.

$$x_0 = \frac{48}{17} - \frac{32}{17}D, \quad (3 - 1)$$

where the x_0 is the initial value for NR algorithm and D is the denominator value for calculating the expression N/D .

Because the fixed point number format $Q32.15$ is used, the fractional numbers in equation 3 - 1 are rounded to 2.8229 (32'sb00000000000000010_110100101011000 in binary) and 1.8819 (32'sb00000000000000001_111000011100101 in binary) respectively.

After the initial value x_0 is calculated, the NR algorithm is performed. The idea for using NR algorithm to calculate the division of N/D is to trade the division for a multiplication, which can be synthetized in the FPGA fabric. For the NR algorithm the function with root is $1/D$ is essential. There may be many functions, which root is the searched value $1/D$ but the most trivial is eq. 3 - 2.

$$F(x) = \frac{1}{x} - D. \quad (3 - 2)$$

For the derivative at the point of x_i then applies eq. 3 - 3.

$$\frac{dF(x_i)}{dx} = F'(x_i) = \frac{F(x_{i+1}) - F(x_i)}{x_{i+1} - x_i}. \quad (3 - 3)$$

Because finding root of the equation 3 - 2, the value of $F(x_{i+1})$ is set to be zero. After separating the x_{i+1} value of the eq. 3 - 3 and derivating the function $F(x_i)$ the obtained algorithm for a value x_{i+1} is obtained from eq. 3 - 4.

$$x_{i+1} = -\frac{F(x_i)}{F'(x_i)} + x_i = -\frac{F(x_i)}{-\frac{1}{x_i^2}} + x_i = (\frac{1}{x_i} - D)x_i^2 + x_i = x_i - Dx_i^2 + x_i = 2x_i - Dx_i^2. \quad (3 - 4)$$

Usually, the iterative algorithm is stopped, when the value $F(x_{i+1}) - F(x_i)$ (called defect) reaches certain value set by the stop condition. However, in this algorithm, the stop condition is not yet implemented. Based on the observation carried on the N-R algorithm the obtained result is sufficient after 5 iterations.

The mathematically expressed algorithm is then transformed into programmable algorithm suitable for FPGA implementation. The top module design for this algorithm is presented in the section *Top module design*, the control and data unit for calculating the value x_{i+1} is presented in the *Allocation and Timing*

3.2 IP Block Design

The design of this unit is consists of 4 main modules:

- the **data unit module**, used for manipulating data and making calculation operations,
- the **control unit module**, used for controlling the **data unit module** and **scaling unit module**,
- **scaling unit module**, used for calculating the number of bits needed for shifting the denominator value to the interval [0.5,1].

3.2.1 Top module design

The top module wraps all of the presented modules (**data unit module**, **control unit module**, **scaling unit module**). The basic structure of connected modules of this top design is depicted in the fig. 3 - 1. Thanks to this wrapper it is possible to test the created modules with Verilog Testbench, Verilator [2] or Cocotb [1].

Figure 3 - 1 Top module design for the division unit module block design.

3.2.2 Allocation and Timing

The diagram of the data flow and timing of the algorithm is displayed in the Figure 3 - 2.

The whole algorithm consists of nine steps. The first four steps are used for calculating the initial value of x_0 as described in the equation 3 - 1. The steps $S4$ to $S8$ are for calculating the next search value of x_{i+1} , the root of the equation 3 - 2 so the searched value of $1/D$. The following iteration begins at the step labeled as $S5$. The iterative process continues until a predefined stop condition is met, such as reaching a specified number of iterations.

Figure 3 - 2 Allocation and timing diagram for the Data Path Unit part of the division module.

3.2.3 Data Path Module

The structure of the Data Path Module is depicted in the Figure 3 - 3. The module was specifically designed to serve the needs of the division algorithm. It comprises five registers labeled $R0$ through $R4$, two multipliers $M1$, $M2$ and one bit shifter.

The module is controlled by the control unit with the control signal labeled as CS . The encoding table with the labels which corresponds to the Data Path Unit module is presented in the section *Control Unit*.

The result of each iteration from the division algorithm is passed to a register $R0$.

The Data Path Module unit also covers the possibility of negative denominator and numerator. Because the values are stored in a custom $Q32.15$ fixed point format (whole number comprises of 32 bits, 15 bits fractional part, 17 bits integer part), the algorithm checks if the D or N values are higher than $0h8000$ and determine it's actual sign and the sets sign of the result. If the analyzed number is determined negative, it is transformed to value positive and then used in the presented division algorithm. This transformation is needed because of the algorithm calculating the bits to shift the denominator in the interval.

Figure 3 - 3 Register Transfer Level (RTL) scheme of the Data Path Unit part of the division module.

3.2.4 Control Unit

The signals from Control Unit to Data Path Module are encoded in the CS signal. The CS signal with the corresponding instructions for the steps S_0 – S_8 of the FSM is presented in the table 3 - 1. For cleaner code, the signal is passed to the Control Unit in the hexadecimal format.

The number of the iteration is also set in the Control Unit. The value is used in this module to determine the stop condition of the calculation.

As stated in the *Allocation and Timing* section, after the step S_8 , the FSM restarts at the state S_4 with new x_i values to be used in the current iteration. This jump is not depicted in the table for CS signal.

Table 3 - 1 Control signal encoding table for instructions to be processed by the Division Module.

3.3 Calculating number of bits to shift the denominator

As presented in the section *Newton Rapshon algorithm for calculating the division* the denominator must be appropriately scaled for the division algorithm to work. This section presents algorithm for scaling the denominator specified in the fixed point number format *Q32.15*. After the scaling value is successfully determined, the numerator is scaled accordingly.

The presented algorithm shifts the value of denominator at every positive edge of the clock signal and saves the shifted value in the `compare` register. Then the combinational circuit is utilized to compare the shifted value in `compare` register with the number 1 specified in *Q32.15* format. If the compared value is the same or lower than 1 the shifting algorithm is done and the value `scaleToShift` is successfully found. If not, the inner value of shifting bits is incremented and the algorithm proceeds to the next iteration.

The presented algorithm is realized in the *denominatorSizeScaleUnit* module and its pseudocode is depicted in the code 3 - 1.

```
1  at every negative edge of clock or positive edge of reset
2  if(rst)
3      scaleToShift = 0;
4      scaleToShiftInternal = 1;
5      started = 0;
6  end if
7  else if (start)
8      started = 1;
9  end else if
10
11  at every positive edge of clock
12  if (compare <= 32'b000000000000000001_0000000000000000)
13      done = 1;
14      started = 0;
15      scaleToShift = scaleToShiftInternal;
16  end if
17  else
18      done = 0;
19      scaleToShiftInternal = scaleToShiftInternal + 1;
20  end else
```

Code 3 - 1 Pseudocode for the *denominatorSizeScaleUnit* module algorithm.

3.4 Simulation results

The simulation via Verilog testbench was made to determine the correctness of presented division module. The Icarus Verilog simulator was used to simulate the module and GTKWave was used to display the VCD simulation output file.

As for the simulation output it can be stated, that the module works correctly for positive and negative numbers of fixed point format *Q32.15*.

The algorithm used in this module is able to calculate the proper result in much less clock cycles than the full division algorithm used in the division module in the package [3].

Thus the presented module may be used as a submodule in more complex modules.

```

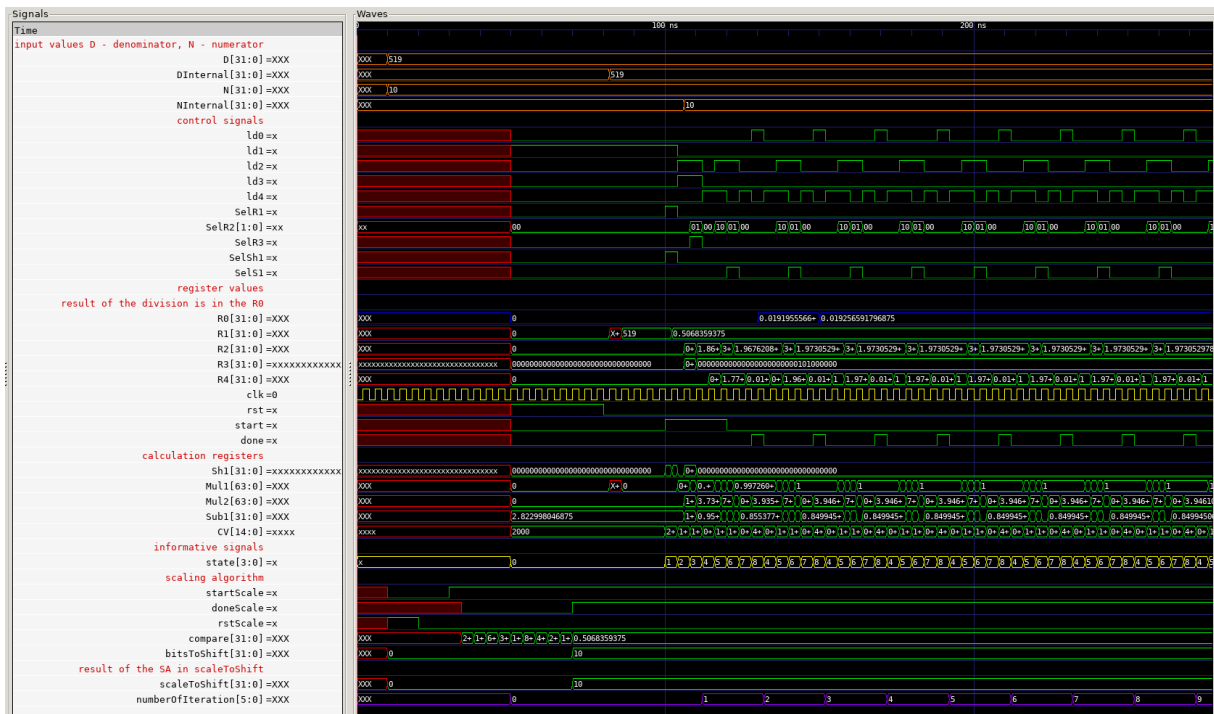

Figure 3 - 8 Selected signals of simulation of division $N/D = 10 / (519)$. The correct result in R0 is obtained after two iterations (reg numberOfIterations).

4 Using CORDIC to calculate trigonometric functions

There are numerous ways how to calculate the trigonometric functions. To gain more flexibility the Coordinate Rotation Digital Computer (CORDIC) was chosen above the Look-Up Table (LUT) implementation.

The LUT method may be fast, but the accuracy depends on the size of the table. When using the CORDIC the precision depends on number of performed iterations of the algorithm. The modified algorithm may be used to calculate non-trivial functions, such as hyperbolic functions, square roots, multiplications, divisions, exponentials and logarithms. [4] In this work only the calculation of *sinus* and *cosinus* functions is used.

4.1 Theory

The theory of the first CORDIC was proposed by Volder in [5]. This algorithm computes a coordinate conversion between rectangular (x, y) and polar (R, θ) coordinates. The algorithm was then generalized by Walther in [6] to include circular, linear and hyperbolic transforms. This paper utilizes only circular transforms to calculate *sinus* and *cosinus* functions. Only the most basic approach of the algorithm will be presented.

The rotation of a vector in the rectangular coordinate system (x, y) may be described by matrix-vector multiplication depicted in the eq. 4 - 1.

$$\begin{pmatrix} x_R \\ y_R \end{pmatrix} = \begin{pmatrix} \cos(\theta) & -\sin(\theta) \\ \sin(\theta) & \cos(\theta) \end{pmatrix} \begin{pmatrix} x_{in} \\ y_{in} \end{pmatrix}, \quad (4 - 1)$$

where x_R and y_R are coordinates of a rotated vector, θ is the angle for which the vector with coordinates x_{in} and y_{in} was rotated.

Then when simplifying the equation

$$\begin{pmatrix} x_R \\ y_R \end{pmatrix} = \cos(\theta) \begin{pmatrix} 1 & -\tan(\theta) \\ \tan(\theta) & 1 \end{pmatrix} \begin{pmatrix} x_{in} \\ y_{in} \end{pmatrix} \quad (4 - 2)$$

it can be seen, that only multiplication by scaling factor of precalculated values of $\cos(\theta)$, multiplication by $\tan(\theta)$, subtraction and addition operations are needed. However, the multiplication by $\tan(\theta)$ can be interchanged. The interchange may be done for angles θ for which the equation 4 - 3 is true. The when implementing the algorithm to the FPGA the multiplication may be swapped for signed right bit shift.

$$\tan(\theta) = 2^{-1}. \quad (4 - 3)$$

When the values $x_{in} = 1$ and $y_{in} = 0$ are used, the result for *sinus* and *cosinus* may be easily obtained from x_R and y_R as expressed in the equation 4 - 4.

$$\begin{aligned} x_R &= x_{in} \cos(\theta) - y_{in} \sin(\theta) = |\theta = 0| = \cos(\theta) \\ y_R &= x_{in} \sin(\theta) + y_{in} \cos(\theta) = |\theta = 0| = \sin(\theta) \end{aligned} \quad (4 - 4)$$

The algorithm may be further simplified by expecting that the algorithm is designed to use more than 6 iterations and thus the scaling constant represented by multiplying *cosinus* of different θ values converges to 0,60725. So there is no need to precalculate all the scaling values only the convergent value may be used. In this paper the precalculated values are passed from the custom LUT module to the

main algorithm.

As can be seen from the section *Example of calculation* section or the algorithm theory itself, it needs to be determined, if the angle for which the vector is rotated in the next iteration should be in a positive direction (counter-clockwise) or negative direction (clockwise). For that, the set of the equations is expanded and new value z_i added. The complete set of equations which are used in the implementation are as follows.

$$\begin{aligned} x[i+1] &= x[i] - \sigma_i 2^{-i} y[i], \\ y[i+1] &= y[i] + \sigma_i 2^{-i} x[i], \\ z[i+1] &= z[i] - \sigma_i \operatorname{atan}(2^{-i}). \end{aligned} \quad (4-5)$$

The σ_{i+1} is determined based on the sign of the z_{i+1} variable

$$\sigma_{i+1} = \begin{cases} -1, & \text{if } z_{i+1} < 0 \\ 1, & \text{if } z_{i+1} > 0 \\ 0, & \text{if } z_{i+1} = 0 \end{cases} \quad (4-6)$$

The algorithm as presented calculates the correct values for *sinus* and *cosinus* functions only in the first and fourth quadrant ($3\pi/2$ to $\pi/2$ counter-clockwise). For usage in the whole 2π range, corresponding actions before the 0. iteration must be made.

The algorithm must make checks, to determine the quadrant, where the desired angle θ for which the *sinus* and *cosinus* functions are to be calculated. This is done by `if` statements at the algorithm values initialization and at the final function value calculation. If the desired argument of the functions is not in the first or fourth quadrant then the angle is transferred from the actual quadrant to the first or fourth quadrant. Based on the quadrant, to which the angle is transformed, the σ_i value is set. The corresponding `if` statements at the algorithm initialization are presented in the pseudocode 4 - 1.

Similar `if` statements are used at the final calculation of *sinus* and *cosinus* values. The `if` statements are presented in the pseudocode 4 - 2.

The pseudocodes use `initialZValue` as a desired angle θ , for which to calculate the function values, `zValue` as a temporary value for calculating the iterations for z_i variables, `sigmaValue` for temporary value holding the current iteration value of σ_i , the `resultCos` and `resultSin` variables are used for storing the temporary and final values of the $\cos(\theta)$ and $\sin(\theta)$ values respectively.

```

1  if((initialZValue > 1.5707)&(initialZValue < 3.141592))
2      sigmaValue = -1
3      zValue = initialZValue - 3.141592
4  else if((initialZValue > 3.141592)&(initialZValue < 4.7123))
5      sigmaValue = 1
6      zValue = initialZValue - 3.141592
7  else

5   resultCos = - resultCos
6   resultSin = - resultSin
7 end

```

Code 4 - 2 Pseudocode for if statements used at the final *sinus* and *cosinus* value calculation.

4.1.1 Example of calculation

The general approach of CORDIC algorithm may be explained on the example for calculating the *sinus* and *cosinus* values for the angle $\theta = 57,535^\circ$. Firstly, the angle may be destructurized in the base angles, for which the equation 4 - 3 is true. In this example the is destructurized as $57,535 = 45 + 25,565 - 14,03$.

The index i of the variables x_i and y_i in the following equations means the number of iteration of the algorithm.

$$0. \text{ iteration } \begin{pmatrix} x_0 \\ y_0 \end{pmatrix} = \cos(45^\circ) \begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} x_{\text{in}} \\ y_{\text{in}} \end{pmatrix}, \quad (4 - 7)$$

$$1. \text{ iteration } \begin{pmatrix} x_1 \\ y_1 \end{pmatrix} = \cos(25,565^\circ) \begin{pmatrix} 1 & -2^{-1} \\ 2^{-1} & 1 \end{pmatrix} \begin{pmatrix} x_0 \\ y_0 \end{pmatrix}, \quad (4 - 8)$$

$$2. \text{ iteration } \begin{pmatrix} x_2 \\ y_2 \end{pmatrix} = \cos(-14,03^\circ) \begin{pmatrix} 1 & -2^{-2} \\ 2^{-2} & 1 \end{pmatrix} \begin{pmatrix} x_1 \\ y_1 \end{pmatrix}. \quad (4 - 9)$$

Then after substitution the value of x_2 and y_2 may be obtained.

$$\begin{pmatrix} x_2 \\ y_2 \end{pmatrix} = \cos(45^\circ) \cos(25,565^\circ) \cos(-14,03^\circ) \begin{pmatrix} 1 & -2^{-2} \\ 2^{-2} & 1 \end{pmatrix} \begin{pmatrix} 1 & -2^{-1} \\ 2^{-1} & 1 \end{pmatrix} \begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} x_{\text{in}} \\ y_{\text{in}} \end{pmatrix}. \quad (4 - 10)$$

From the equation 4 - 10 the values x_2 and y_2 represent the value of $\cos(57,535^\circ)$ and $\sin(57,535^\circ)$ respectively.

4.2 Python Implementation

The CORDIC algorithm was for simplicity prototyped in python. This turned out very beneficial as the debugging of the code is much faster. The less complex and abstract python code may help with understanding and creating the designed algorithms more than Mathematica which uses some higher abstraction layers to make calculations optimized and easier for more complex problems. But when designing the low level mathematical algorithms, the lower and easier language the more easy is then to implement the design in Verilog or any other hardware description language.

The python code was as well used to precalculate the LUT for scaling factor and arcus tangens values for z_i calculations.

For the clarity, the python implementation is presented in the code 4 - 3. The code also calculates the error of the CORDIC calculated value from the python math library functions.

```

1 import math

```

```

$Q32.15$ format is required.

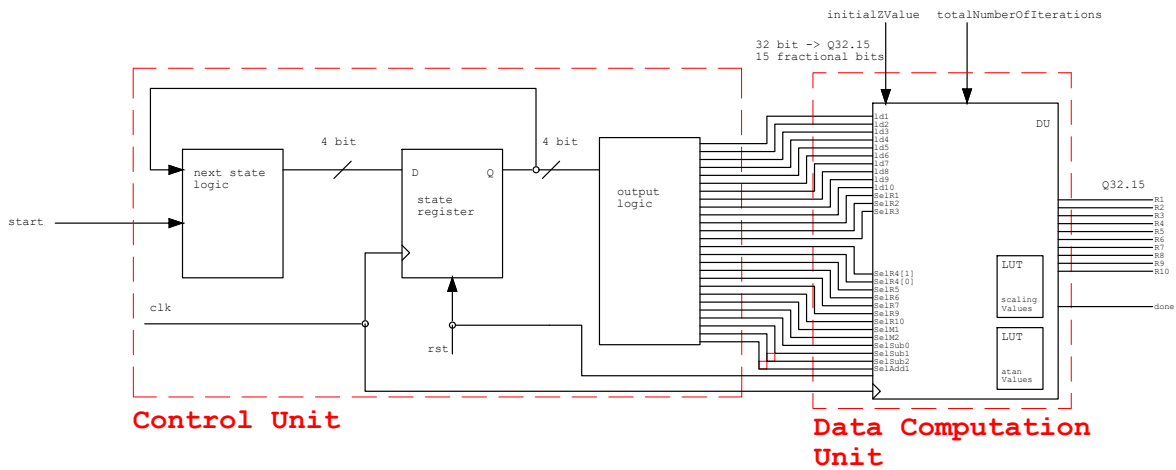

Figure 4 - 1 Top module design for the CORDIC module block design.

4.3.2 Allocation and Timing

In the picture 4 - 2 the allocation and timing diagram is depicted. As can be seen, the if statements which are implemented in the control unit are documented here as well. The explanation why the if statements are needed is stated in the *CORDIC Theory* section. As stated in the section for *CORDIC Control Unit* there are two approaches of iteration cycles. The designer may choose jump from *S4* to *S2* for faster algorithm or from *S6* to *S2* for demonstrative approach. The jumps in the allocation and timing diagram are not shown.

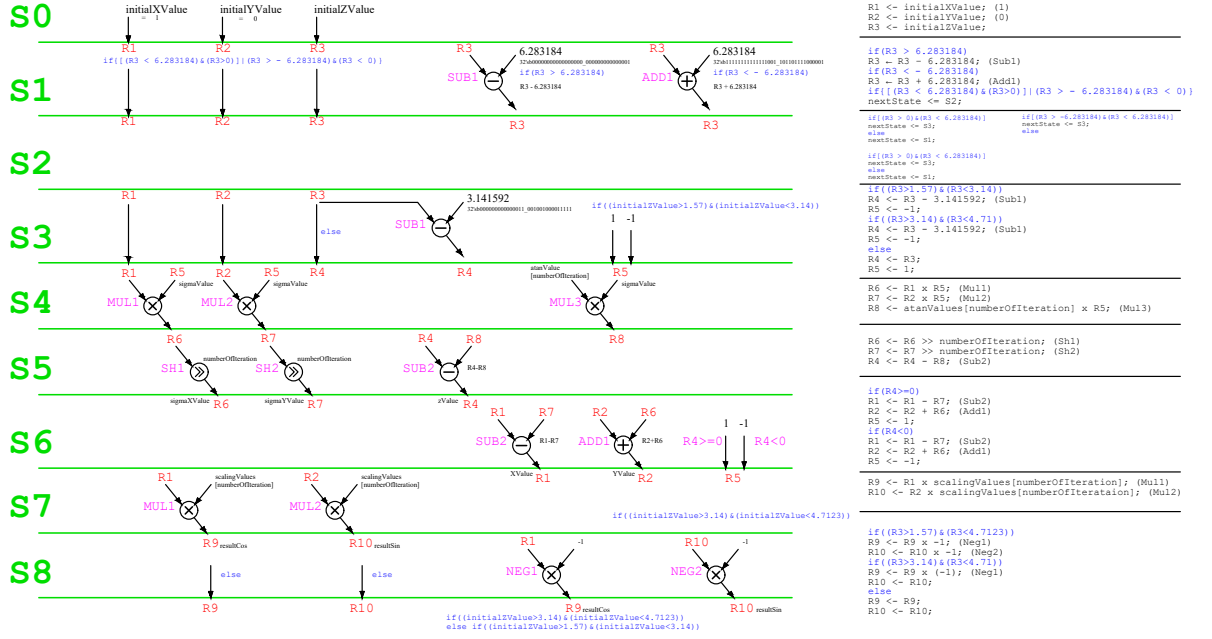

Figure 4 - 2 Allocation and timing diagram for the Data Path Unit part of the CORDIC IP.

4.3.3 Data Path Module

The picture 4 - 3 visualize the Data Path part of the Top Module design including calculation and storing units. The memory LUTs for *atanValues* and *scalingValues* are not depicted as a separate registers but as inputs to the calculation units. The results of *sinus* and *cosinus* functions, in python implementation named as *resultSin* and *resultCos* are saved to registers R9 and R10. The **NEG** blocks aren't in fact implemented as a standalone blocks for making negative numbers. The negation is activated in a corresponding target register when the appropriate **SelR_x** is activated. (where *x* is here the number of a corresponding register R9 or R10)

As was stated before, the implementation of the LUT memory module for *atanValues* is depicted in Code 4 - 4, memory module for *scalingValues* is depicted in Code 4 - 5.

Code 4 - 5 Verilog code of the scalingValuesCordicLUT lookup table (LUT) implementation.

4.3.4 Control Unit

Same way as in a Division Module Control unit, presented in *Control Unit* section, the control signal encoding table 4 - 1 for Data Path CORDIC unit is created.

The branches of if statements used in the design has been colorcoded in the table for improved clarity. The iteration jumps are not depicted in the control signal table. The jumps may be performed from the step *S4*, when the speed of the calculation is the main concern, or from *S6*, when the algorithm function is presented. The steps *S5* and *S6* are mainly focused on multiplying the result of iteration by the appropriate scaling value and on transforming the results based on the quadrant of the original wanted angle value.

Table 4 - 1 Control signal encoding table for instructions to be processed by the CORDIC Module.

4.4 Simulation results

The testbench for testing the design is created with cocotb and simulated with Verilator.

As can be seen when implementing the algorithm where the actual iteration value for *sinus* and *cosinus* is calculated, the number of cycles needed for the final calculation can be calculated

$$NoCyc_{result \text{ every iteration}} = \left\{ \begin{array}{l} 3, \text{ if } initialZValue \in [-2\pi, 2\pi] \\ 4, \text{ if } initialZValue \notin [-2\pi, 2\pi] \end{array} \right\} + 5NoIt, \quad (4 - 11)$$

where *NoCyc* (-) is the number of cycles and *NoIt* is the number of iterations for the CORDIC algorithm. The 4 value is for *S0-S4* and the multiplication by 5 is because of states *S4-S8*. When the

result of the CORDIC algorithm is calculated only once at the end of the algorithm, the number of iteration can be determined by

$$NoCyc_{\text{result at the end}} = \begin{cases} 3, & \text{if } initialZValue \in [-2\pi, 2\pi] \\ 4, & \text{if } initialZValue \notin [-2\pi, 2\pi] \end{cases} + 3NoIt + 2, \quad (4 - 12)$$

where the multiplication by value 3 is caused by states $S4-S6$, the addition of 4 is caused by states $S0-S4$ and the addition of the 2 is caused by states $S7-S8$.

In the simulation the *numberOfCycles* displayed is more of an index of the cycle, so for angle θ is the number of iterations depicted on Figure 4 - 5 in fact 63 not displayed 62.

The frequency of the clock signal in this design is currently set as 50 MHz.

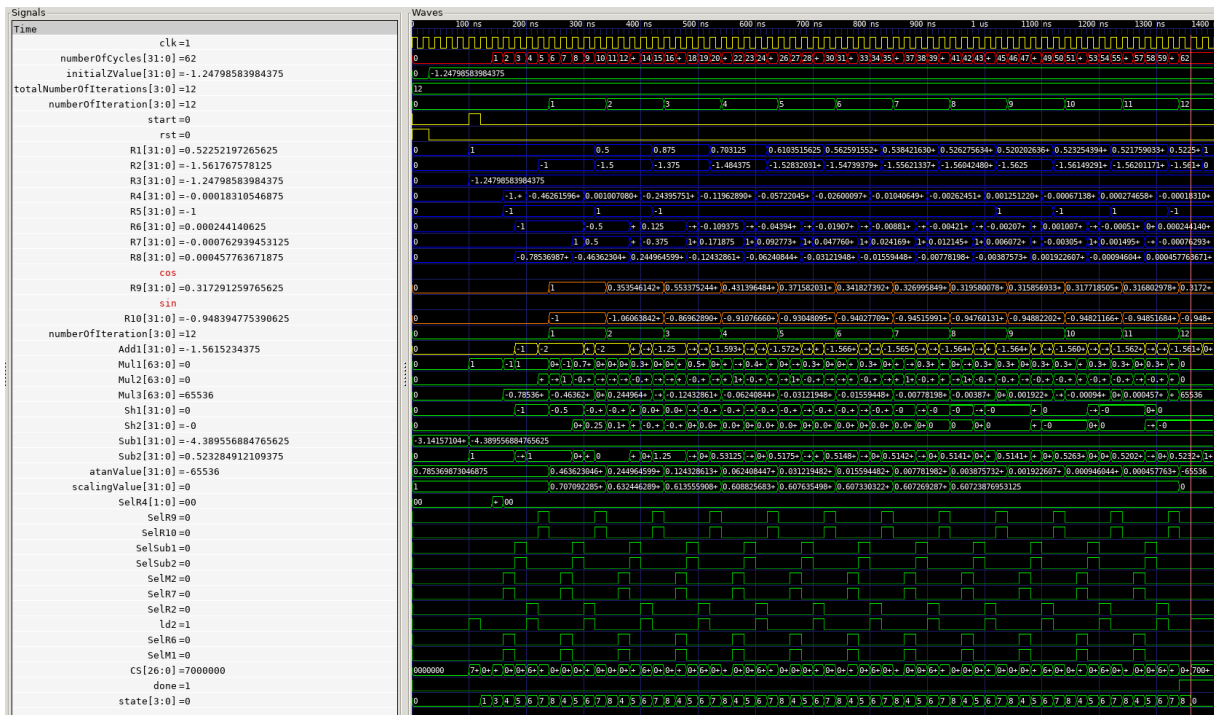

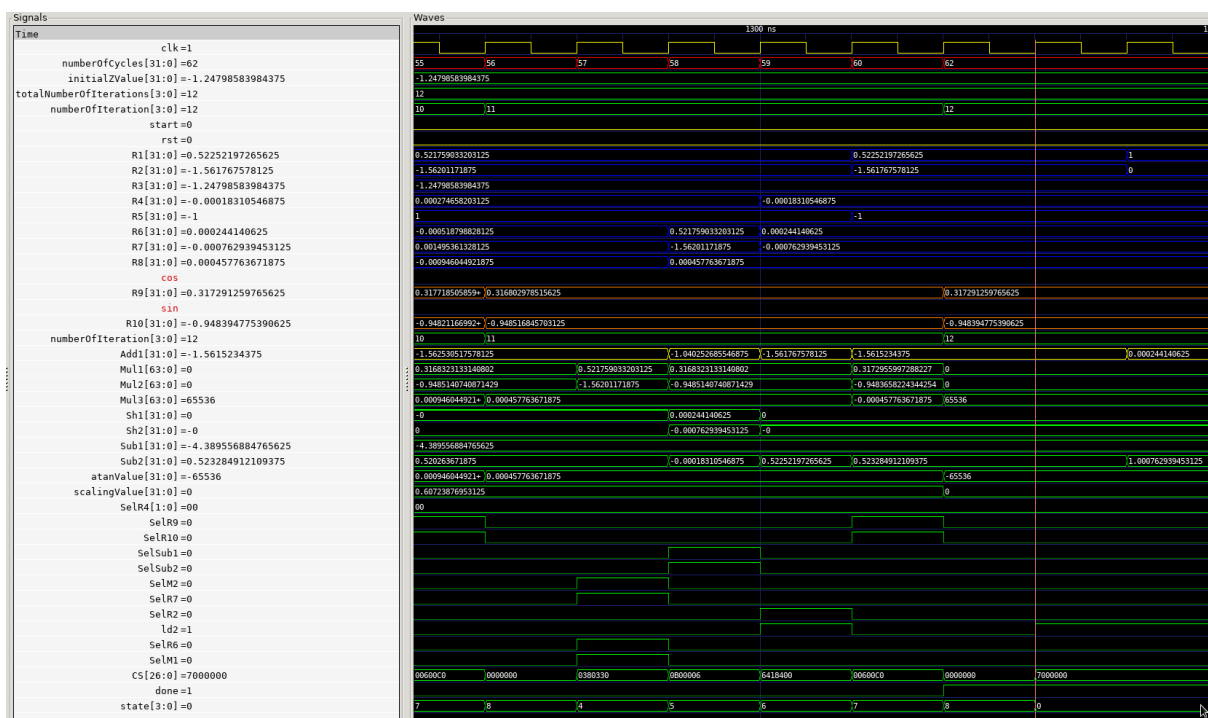

Figure 4 - 4 The whole Verilog simulation of CORDIC algorithm for determining the sinus and cosinus values of angle $\theta = -1.2479$ rad. The value of sinus and cosinus based on the current iteration is also calculated in this algorithm approach. The result is passed to the registers R9 and R10.

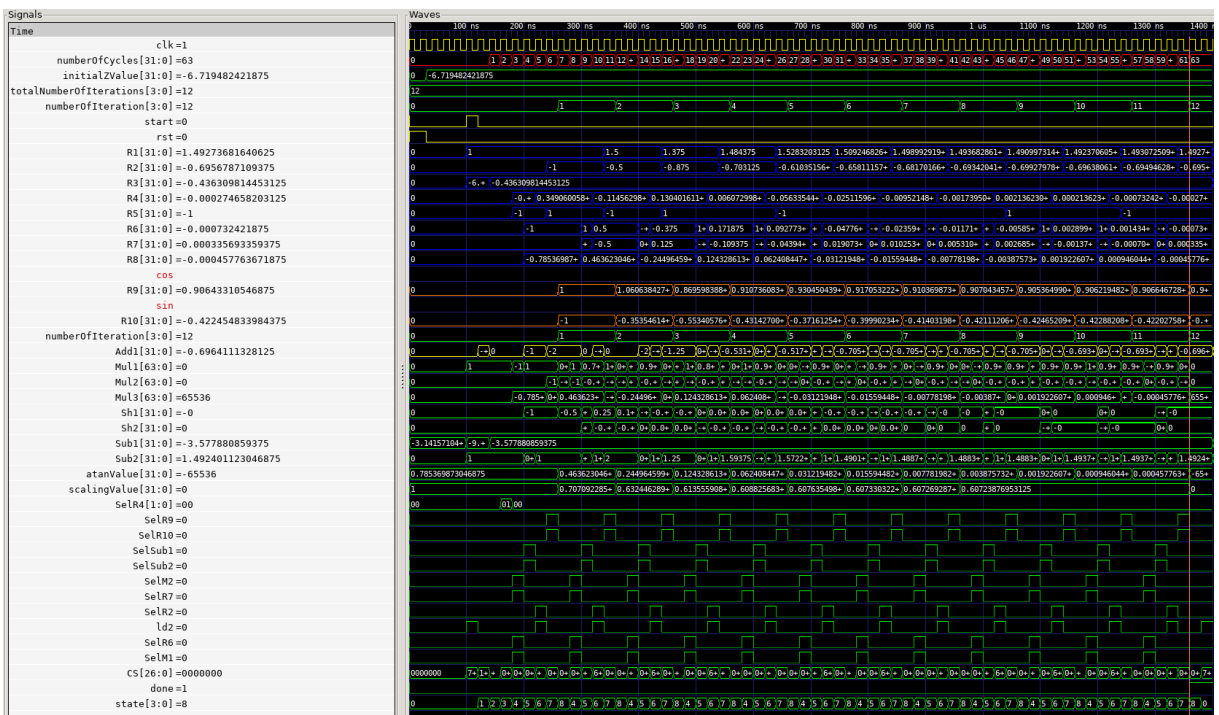

Figure 4 - 7 The whole Verilog simulation of CORDIC algorithm for determining the sinus and cosinus values of angle $\theta = -6.7195129$ rad. The value of sinus and cosinus based on the current iteration is also calculated in this algorithm approach. The result is passed to the registers R9 and R10.

5 Simple set of nonlinear equations solved by a Newton-Raphson algorithm using custom circuit implementation

All the presented parts in previous sections may be utilized to solve the system of nonlinear equations. This work leads to solving the transcendental equations for Selective Harmonic Elimination. But the best approach is to firstly solve an easier set of equations to determine, if the approach of NR is viable.

5.1 Theory

The objective of the NR algorithm is to solve the set of nonlinear equations

$$F_1(x_1, x_2) = x_1^3 - x_2 - 1, \quad (5 - 1)$$

$$F_2(x_1, x_2) = x_1 - 2x_2 - 2, \quad (5 - 2)$$

where one possible set of solutions x_1 and x_2 yields

$$F_1 = 0, \quad (5 - 3)$$

$$F_2 = 0. \quad (5 - 4)$$

The algorithm could be implemented in a custom CPU with reduced instruction set but for the obvious reasons, eg. speed and complexity of developing own RISC-V, the approach of creating the application specific circuit design was used.

To be able to implement the algorithm to the custom design, the general NR algorithm approach had to be simplified to the most low level implementation. Every single part that could be precalculated was set as a static value at the design step.

To check if the implementation and algorithm was well designed, the solution by *Solve* function and a customized NR was made in Wolfram Mathematica. Before the start of the algorithm the starting values of x_1^0 and x_2^0 were set as an input to the module. Based on that input the function values at selected starting points were calculated.

As a next step, the so called defect could be calculated using the newly found values of $F_1(x_1^0)$ and $F_2(x_1^0, x_2^0)$

$$\Delta \mathbf{F}^i = \begin{pmatrix} \Delta F_1^i \\ \Delta F_2^i \end{pmatrix} = \begin{pmatrix} F_1^i - F_1^{\text{known solution}} \\ F_2^i - F_2^{\text{known solution}} \end{pmatrix}, \quad (5 - 5)$$

where the superscript i is the number of iteration for which the defect is calculated. When the algorithm starts, the $i = 0$. So for example the input value for F_1^0 is x_1^0 and x_2^0 .

Next the Jacobian matrix \mathbf{J} from vector of functions $(F)(x_1, x_2) = (F_1, F_2)$ is calculated as follows.

$$\mathbf{J}^i = \begin{pmatrix} \frac{dF_1}{dx_1^i} & \frac{dF_1}{dx_2^i} \\ \frac{dF_2}{dx_1^i} & \frac{dF_2}{dx_2^i} \end{pmatrix} = \begin{pmatrix} 3(x_1^i)^2 & -1 \\ 1 & -2 \end{pmatrix}. \quad (5 - 6)$$

As for the general NR algorithm, the inverted value of Jacobian matrix needs to be calculated. The problem is that when using general mathematical software, such as Wolfram Mathematica, the calculation of the inverted value is as easy as using function of inversion. When designing the circuit, the approach of

manual calculation of inversion must be used. In this paper, the calculation is made possible by calculating the determinant of the Jacobian Matrix, its reciprocal value, its adjugate matrix and multiplication of the adjugate matrix elements by the calculated determinant reciprocal value.

Because the size of the Jacobian matrix is 2x2 the determinant may be easily calculated using the Sarrus Rule. When the matrix is more complicated, the expansion method may be utilized.

$$\det(\mathbf{J}) = 3(x_1^i)^2(-2) - (-1) = 3(x_1^i)^2(-2) + 1. \quad (5 - 7)$$

The reciprocal value of the determinant is then calculated by the Division Unit, created for calculating division of arbitrary numbers real numbers. This Division Unit is presented in the section *Calculating the division of fixed point numbers*.

The adjugate matrix is calculated as follows

$$\text{adj}(\mathbf{J}) = \begin{pmatrix} \mathbf{J}_{11}(-1)^{1+1} & \mathbf{J}_{01}(-1)^{1+2} \\ \mathbf{J}_{10}(-1)^{1+2} & \mathbf{J}_{00}(-1)^{2+2} \end{pmatrix} = \begin{pmatrix} -2 & -1 \\ 1 & 3(x_1^i)^2 \end{pmatrix}. \quad (5 - 8)$$

After the calculation of the reciprocal value of the determinant of the Jakobi matrix and the adjugate matrix, the inverted Jakobi matrix bay be finally calculated

$$\mathbf{J}^{-1i} = \frac{1}{\det(\mathbf{J}^i)} \begin{pmatrix} \text{adj}(\mathbf{J}_{00}^i) & \text{adj}(\mathbf{J}_{01}^i) \\ \text{adj}(\mathbf{J}_{10}^i) & \text{adj}(\mathbf{J}_{11}^i) \end{pmatrix} = \frac{1}{\det(\mathbf{J}^i)} \begin{pmatrix} -2 & -1 \\ 1 & 3(x_1^i)^2 \end{pmatrix}. \quad (5 - 9)$$

Next the $(\Delta x_1^i, \Delta x_2^i)$ is to be calculated by using the inverted Jacobi matrix and the defect.

$$\begin{pmatrix} \Delta x_1^i \\ \Delta x_2^i \end{pmatrix} = \begin{pmatrix} \mathbf{J}_{00}^{-1i} \Delta F_1^i + \mathbf{J}_{01}^{-1i} \Delta F_2^i \\ \mathbf{J}_{10}^{-1i} \Delta F_1^i + \mathbf{J}_{11}^{-1i} \Delta F_2^i \end{pmatrix}. \quad (5 - 10)$$

Now the next iteration value denoted as $i + 1$ of x_1 and x_2 may be calculated

$$\begin{pmatrix} x_1^{i+1} \\ x_2^{i+1} \end{pmatrix} = \begin{pmatrix} x_1^i + \Delta x_1^i \\ x_2^i + \Delta x_2^i \end{pmatrix}. \quad (5 - 11)$$

With those new iteration values x_1^{i+1} x_2^{i+1} the loop for calculation starts again at the calculation of the new value F_1^{i+1} F_2^{i+1} which is presented at the start of this section.

5.2 IP Block Design

5.2.1 Top module design

The picture 5 - 1 depicts the top module design of the circuit. The Control Unit sends control signals to the Data Path unit to make the desired calculations. As in all designs in this paper, the numbers are formatted in the *Q32.15* fixed point format.

Figure 5 - 1 Top module design for the simple Newton-Raphson (NR) calculation unit module block design.

5.2.2 Allocation and Timing

The algorithm structure for the Verilog implementation is depicted in the data flow diagram in the picture 5 - 2. The algorithm iteration jumps (explained in the section *Control unit* of the simple NR algorithm) are not displayed in this diagram.

Figure 5 - 2 Allocation and timing diagram for the Data Path Unit part of the simple (NR) module.

5.2.3 Data Path Unit

The Data path unit for this simple NR algorithm consists of four multipliers, two adders, two subtractors and one divider. The divider is implemented using the Division Unit, presented in the section *Calculating the division of fixed point numbers*. When the algorithm has finished the results for x_1 and x_2 are saved in the R1 and R2, the state S11 is set and *done* signal is set to 1. The results then can be driven to another module or unit for further usage. In fact the *done* signal is driven in the Control Unit and can be used in controlling the possible module, where the NR module is only part of the design.

Figure 5 - 3 Register Transfer Level (RTL) scheme of the Data Path Unit part of the simple Newton-Raphson (NR) calculation IP.

5.2.4 Control Unit

The encoding table 5 - 1 shows the steps of the algorithm with a corresponding control signal for the Data Path Unit of the simple NR algorithm Verilog implementation.

The NR algorithm iteration jumps are carried out from the state *S10* to state *S1*, when the numebr of iteration is lower than the set total number of iterations, which is hardcoded to the Control Unit. At this implementation, the total number of iterations is se to be 5. In fact, the end of the NR algorithm should be determined based on the defect value. In this simple example, the value check of the defect is not implemented. The implementation would be simple though. The value of register holding the defect values R3 and R4 would be wired to the control unit in the corresponding steps *S4* and *S5* respectively and the comparison with the desired defect value would be performed. If the defect value was smaller than the desired value, the next state of the algorithm would be *S11* and therefore the calculation would end. If the defect was larger than the desired value, the next state would be *S6* and the iteratioun would complete normally and loop from the state *S10* to *S1*.

Table 5 - 1 Control signal encoding table for instructions to be processed by the simple Newton-Raphson (NR) alorithm solve Module.

5.3 Simulation results

The test bench for simulation was made using Cocotb [1] with the Verilator [2] as a simulator. The result of the calculation may be seen in the registers R1 and R2. The results are $x_1 = -0.707489$ and $x_2 = -1.353759$

The clock signal frequency for this design is currently 20 MHz.

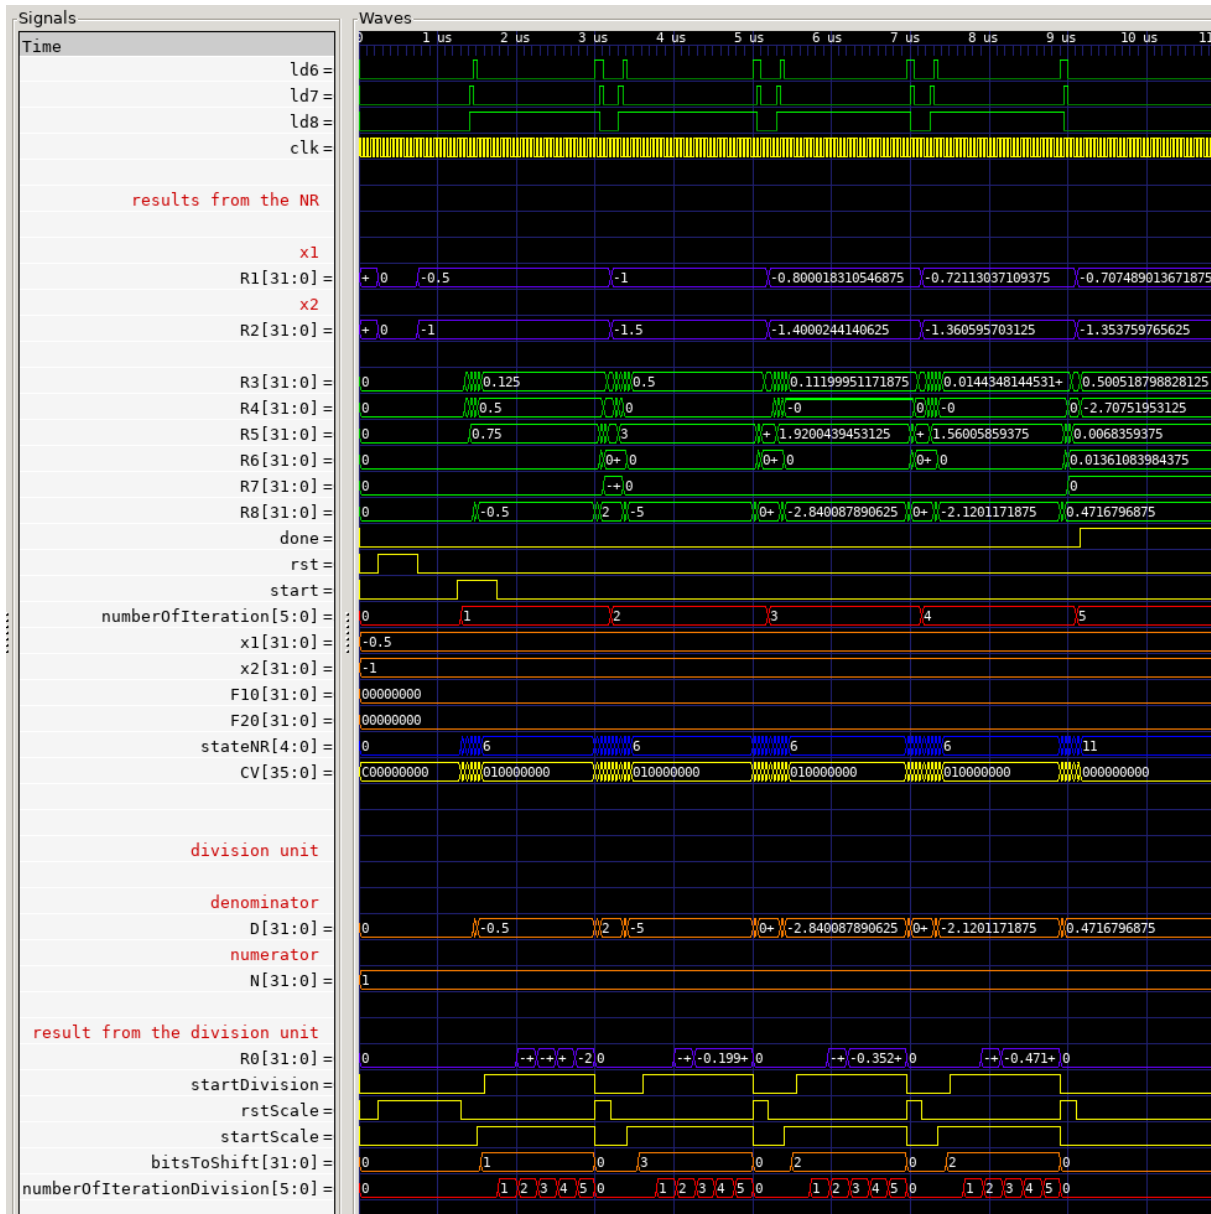

Figure 5 - 4 The whole Verilog simulation of a simple Newton-Raphson (NR) algorithm. The result is may be seen in registers R1 and R2 after the fifth iteration of the algorithm.

6 Selective Harmonic Elimination

6.1 Theory

6.2 IP Block Design

6.2.1 Algorithm Block Diagram

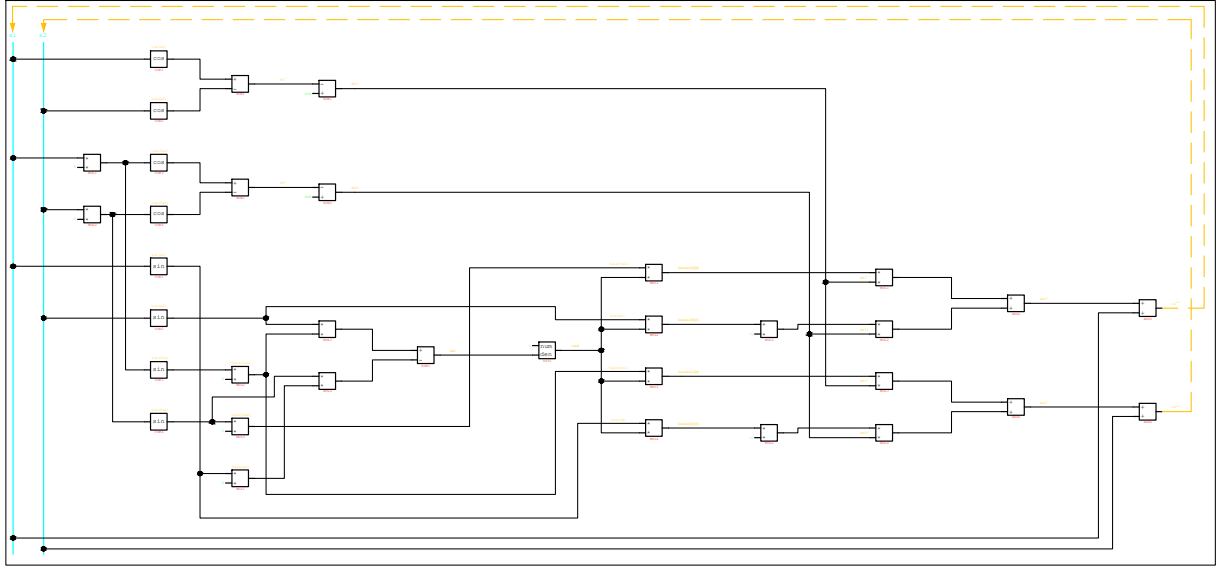

Figure 6 - 1 Block Diagram of the Selective Harmonic Elimination (SHE) using Newton-Raphson algorithm.

6.2.2 Top module design

The top module of this IP is very similar to other developed modules for this paper. The design consists of a Control Unit which sends control signals to the Data Unit. The Data Unit, which consists of registers and computational units incorporates few external sub modules for additional calculations, such as CORDIC and division.

As for every design presented, the units utilize the $Q32.15$ fixed point format for its computational units and registers, the exception being multiplier computational units, which by the principle of multiplication use format $Q64.30$ for the results. When the multiplication results are passed to registers, the values are rounded back to globally used format.

The design is depicted on Figure 6 - 1.

6.2.3 Allocation and Timing

The Allocation and Timing diagram, depicted on Figure 6 - 2 describes the algorithm presented in the *Theory* section. As can be seen from previous sections, this algorithm has been thoroughly tested before Verilog implementation.

The Verilog implementation consists of totally 13 states $S0-S12$. Through states $S1-S11$ the NR algo-
